## Study Title:

FISHERIES INVESTIGATIONS IN LAKES AND STREAMS STATEWIDE

Job Title:
Contribution of South Carolina and Georgia stocked hybrid bass in Lakes Hartwell and Thurmond.

Period Covered July 1, 2002 - December 31, 2003

## Results and Discussion

In last years report we examined the contribution of South Carolina Department of Natural Resources (SCDNR) and Georgia Department of Natural Resources (GADNR) stocked hybrid striped bass to the 1999 year class in Lakes Hartwell and Thurmond. Results showed that the proportion of SCDNR hybrids in the catch at age $0+$ was greater than the proportion stocked for both lakes. However, analysis of the catch at age 1+ indicated equal survival. We considered two possible explanations for the change in relative frequencies of SCDNR and GADNR hybrids from age $0+$ to age 1+. One was differential survival of GA and SC hybrids from the 1999 to the 2000 sampling periods. Another was non-random sampling of SCDNR and GADNR stocked fish at age $0+$ possibly due to gear selectivity for larger fish. In an effort to assess the selectivity of the nets, mesh size and total length were noted for each hybrid collected in the 2002/03 sampling season. Fish collected by South Carolina were also aged.

From Thurmond 180 hybrids were collected and 66 were aged. From Hartwell 35 hybrids were collected and 2 were aged. Due to the small sample size from Lake Hartwell, the data and discussion presented here will focus on Lake Thurmond.

The Thurmond data appears to show a representative sample of age 0 's. The data is normally distributed, with fish ranging from 150-330 mm (Figure 1). More age 1 ( $\mathrm{n}=47$ ) fish were collected
than age $0(n=8)$ however (Table 1). That may be showing that age 0 's aren't as vulnerable to capture, or may be showing some difference in the 2002 and 2001 year classes.

Figure 1. Length frequencies for gill net catch of hybrid striped bass from Lake Thurmond in the 2002-2003 sampling season. Frequencies are shown by 10 mm length group.

Table 1. Gillnet catch and mean total length of aged hybrid striped bass from Lake Thurmond in the 2002/2003 sampling season.

|  |  | Total length -mm |  |  |
| :--- | :--- | :--- | :--- | :--- |
| Age | Number collected | Mean | Range | SD |
| 0 | 8 | 276 | $254-330$ | 28.3 |
| 1 | 47 | 409 | $325-454$ | 23.5 |
| 2 | 3 | 493 | $437-521$ | 48.2 |
| 3 | 5 | 576 | $528-599$ | 29.1 |
| 4 | 1 | 612 | - | - |
| 5 | 2 | 634 | $633-635$ | 1.41 |

Of the three meshes, the largest mesh panel was most effective in 2002-2003 at capturing hybrids, while the smallest mesh panel was relatively ineffective (Figure 2). Most of the age-1 fish collected were captured in the largest mesh panel. Only $5 \%$ of the total catch on Lake Thurmond came from the smallest mesh. Because gillnets were set offshore, alternating the smaller mesh towards and away from shore, the smaller mesh should have had equal opportunity to ensnare fish. We may better target this population by dropping the small mesh and flanking the 1.75 inch mesh with the 1.25 inch and a larger mesh. This is however based on assessment of one year's data. An increased sample size from multiple years can allow us to run statistics on net selectivity, and in the long run ensure we are capturing our target fish most efficiently. Data from multiple years will also allow us to determine whether subsequent year classes follow the same pattern with respect to relative catch frequencies at age 0 to age 1 .

Figure 2. Length frequencies mesh size for gill net catch of hybrid striped bass from Lake Thurmond in the 2002-2003 sampling season. Frequencies are shown by 10 mm length group

## Recommendations

In 2003-2004 continue to note mesh size for each hybrid striped bass collected. Additionally, all fish collected should be aged. This should provide a larger sample size for analysis. After analysis consider what net structure will most effectively capture our target fish.

Assess the contribution of SCDNR and GADNR stocked hybrids to another year class in Lakes Thurmond and Hartwell. This has not been possible recently due to difficulty in discerning marks on known marked fish. Work with personnel at Bayless hatchery to assess effectiveness of the current marking protocol.

# Job Title: Zoogeography of Centrarchidae of the South Atlantic Slope <br> Period Covered July 1, 2002 - December 31, 2003 

## Results and Discussion

We evaluated levels of within and among population diversity for six species from the family Centrarchidae collected from the Savannah, Edisto, Santee, and Pee Dee drainages. Species collected were redbreast sunfish Lepomis auritus, redear sunfish $L$. microlophus, warmouth $L$. gulosus, dollar sunfish L. marginatus, spotted sunfish L. punctatus, and mud sunfish Acantharchus pomotis. For most species we collected 10 individuals per drainage, with those fish coming from two sites within a drainage. Mud sunfish were not collected from Savannah drainage. A total of 223 fish were collected (Table 1.).

Sequences of the ND2 gene were generated for 184 of 223 individuals. The sequences generated did not show any variation in mud sunfish and only a single variant, restricted to a single individual, in dollar sunfish. Variation was shown for redbreast, redear, warmouth and spotted sunfish. A measure of the proportion of variation present within and among drainages, $\Phi_{\mathrm{st} \text {, }}$, was calculated for each species and is shown in Table 2.

Table 1. Sunfish collected in 2002 by species and drainage.

| Species | Drainage | Total collected | No. of sites |
| :---: | :---: | :---: | :---: |
| Redbreast | Pee Dee | 10 | 2 |
|  | Santee | 10 | 2 |
|  | Edisto | 10 | 2 |
|  | Savannah | 10 | 2 |
| Redear | Pee Dee | 10 | 1 |
|  | Santee | 10 | 2 |
|  | Edisto | 10 | 2 |
|  | Savannah | 5 | 1 |
| Warmouth | Pee Dee | 10 | 2 |
|  | Santee | 10 | 2 |
|  | Edisto | 10 | 2 |
|  | Savannah | 10 | 2 |
| Dollar | Pee Dee | 10 | 2 |
|  | Santee | 10 | 2 |
|  | Edisto | 10 | 2 |
|  | Savannah | 10 | 2 |
| Spotted | Pee Dee | 9 | 2 |
|  | Santee | 10 | 2 |
|  | Edisto | 10 | 2 |
|  | Savannah | 10 | 2 |
| Mud | Pee Dee | 9 | 2 |
|  | Santee | 10 | 2 |
|  | Edisto | 10 | 2 |

Table 2. Percentage of genetic variation present within and among drainages for sunfish species collected in 2002.

|  | $\Phi_{\text {st }}$ values |  |
| :--- | :--- | :--- |
| Species | Within drainages | Among drainages |
| Dollar | --- | --- |
| Mud | --- | -- |
| Spotted | 1.00 | 0.00 |
| Warmouth | 0.66 | 0.34 |
| Redbreast | 0.78 | 0.22 |
| Redear | 0.90 | 0.10 |

For those species that showed variation at ND2 the amount of genetic diversity within drainages was relatively high, indicating relatively moderate to high effective population sizes. For redear, redbreast and warmouth, the proportion of variation between drainages indicates moderate genetic divergence among drainages. This seems reasonable since these are the three species studied that are most likely to inhabit main river channels. Redear and redbreast are also the two species most likely to have been affected by human intervention through stocking or population transfer. In comparison, the measure of genetic divergence between major drainages for pygmy sunfish Elassoma boehlkei and E. okatie is around 0.96. For shortnose sturgeon Acipenser brevirostrum it is around 0.04 . Results for spotted sunfish indicate a high level of gene flow between drainages. This is a surprising result for a species that typically inhabits slow moving streams, and is usually uncommon.

The current data is showing frequency differences among the populations studied. To have confidence in the variance components we want to extract for all six species however, it important that we increase the data available for calculating genetic variance. Plans are to increase the number of bases sequenced for each individual, and the number of individuals per drainage. Efforts are also
underway to amplify viral DNA isolated from the tissues collected. This may show more population structure in the spotted, dollar and mud sunfish studied.

## Recommendations

Continuing this study for another year. To increase our ability to detect variation, the number of individuals per drainage and the number of base pairs sequenced should be increased. Viral DNA should be extracted to determine if it is useful in determining population structure for these species. More in depth statistical analysis will be performed on the expanded data set.

# Study Title: SURVEY AND INVENTORY <br> Job Title: Development of Reservoir-Specific Management Models 

Period Covered July 2002 - December 2003

## Results and Discussion

Largemouth bass otoliths were obtained from District 1 (Hartwell 2002 and 2003), District 3 (Boyd Mill Pond 2002, Parr Shoals 2002, and Greenwood 2003), and District 4 (Wateree 2001, Stumpy Pond 2003, and Wylie 2002 and 2003) for verification of ages. Percentage of otoliths read by Eastover ranged from $13 \%$ (Wylie 2002) to 100\% (Wylie 2003), and averaged 50\% across reservoirs and districts. Agreement with district-determined ages varied from $78 \%$ for Parr 2002 to $93 \%$ for Boyd Mill Pond 2002, and averaged $89 \%$. Most disagreements ( $89 \%$ ) were $\pm 1$ yr and resulted from differences in the interpretation of the margin in whole mounts. Otoliths broken through the core and examined in cross section usually provided better resolution of the margin than whole mounts, especially for older fish.

A Microsoft Access ${ }^{\mathrm{TM}}$ program to facilitate standardized input and output of spring electrofishing data was developed and distributed to the districts prior to the 2003 sampling season. Few problems with it were reported, none serious. Spring electrofishing data for 2002 and 2003 were received from Districts 1, 3, 4 and 5 following each sampling season. A SAS program developed to automate data compilation, summary, and reporting was tested using 2003 data. The program has been modified for individual districts or regions but it is not yet ready for distribution. Selected population parameters for the reservoirs for which data were available in 2002 and 2003 are summarized in Tables 1a-d and 2a-d, respectively.

Table 1a-d. Largemouth bass population parameters in selected South Carolina reservoirs, 2002. Parameters in 1a and 1 b were computed from age frequency tables based on single- or multi-year age-length keys, as appropriate.

## Recommendations

1. Compile 1997-2003 data, defining best-available model parameters (i.e. growth, mortality, and recruitment).
2. Transfer largemouth bass management model results to the fisheries districts, making reservoir-specific management recommendations when sufficient data are available.
3. Define an optimal statewide regulation for largemouth bass.
4. Continue to provide verification of otolith aging at Eastover.
5. Evaluate zonal differences in largemouth bass population parameters.

Study Title: SURVEY AND INVENTORY<br>Job Title: Piedmont Stream Survey - Broad River basin<br>Period Covered April 1, 2003 - December 31, 2003

## Results and Discussion

The objectives of the Broad River tributary study are to conduct a comprehensive fish community inventory of the wadeable streams of the upper Broad (U.S. Geological Survey hydrologic unit 3050105) and lower Broad (hydrologic unit 3050106) basins, develop a list of species having the greatest conservation need, and, ultimately, identify opportunities for conducting habitat conservation and/or restoration activities expected to have a beneficial effect on aquatic communities.

A GIS database for the two Broad River basins was constructed to aid in the selection of least impacted sites and to ensure that sites were selected proportionally among ecoregions and basins. The database included information on land use, point-source discharge sites, stream order, ecoregions, drainage basins, and roads.

During fall 2003 eighteen streams were sampled following South Carolina Department of Natural Resources (SCDNR) protocols for sampling fish in wadeable streams (Table 1, Figure 1). At least one site was sampled in each of the five ecoregions present within the two study basins.

A total of 7,487 fish, comprising 38 species and seven families (Table 2), was collected. Bluehead chub and yellowfin shiner were the most abundant species, comprising more than $41 \%$ of the total number of fish collected. Highback chub, redbreast sunfish, rosyside dace, spottail shiner, and creek chub each comprised more than $5 \%$ of the total number of fish collected. Dusky shiner,
pumpkinseed sunfish, chain pickerel and flier were rare; only one individual of each species was collected.

No federally-listed threatened or endangered species were collected. However, three species on the South Carolina Heritage Trust list of fishes of special concern were collected (Table 2).

Physical and chemical habitat data were collected at each site, including, turbidity, temperature, dissolved oxygen, conductivity, and pH . A visual habitat inventory was also conducted at each site. Those data have not been processed.

Table 1. Sites sampled within the Broad River drainage during fall 2003.

Figure 1. Sites sampled in the Broad River Drainage during fall, 2003.

## Recommendations

- Continue study as planned, sampling up to 30 sites in 2004.
- Inspect data to see what was gained from repetitive sampling.
- Merge this data with other 2003 stream survey data to obtain initial look at fish distribution.

# Study Title: SURVEY AND INVENTORY <br> Job Title: <br> Evaluation of hooking mortality and recovery of striped bass held in flow-through live-release tubes 

Period Covered January 1, 2003 - December 31, 2003

## Results and Discussion

This project had two objectives. The first objective was to use sonic transmitters to determine if striped bass held in tubes exhibited differential survival from fish caught and immediately released. The second objective was to inspect blood chemistry to determine if fish held in tubes recovered from the stress of capture and handling.

Sample sizes were much lower than anticipated. During the winter (12 February - 3 April) we planned to include up to 96 fish in the study. Approximately half were to be used for blood chemistry analysis and half were to be fitted with sonic transmitters and tracked. Difficulties collecting fish with angling gear limited our sample size to 42 fish, of which 28 were used for blood work (Table 1) and 14 were fitted with transmitters (Table 2). During the summer (30 June - 6 August) 91 fish were collected with angling gear. Thirty-five fish were used for blood work (Table 1) and 45 fish were fitted with sonic transmitters (Table 2).

During the winter all fish placed in tubes were released alive. Of the 14 fish fitted with temperature sensing transmitters, two were never located and 12 were located at least once. Twelve fish survived for at least 3 days while 10 of 12 were re-located and alive after seven days (Table 2). One fish was known to expire 7 days post tagging. During the summer 11 fish died while being held in the tubes. Of the 45 fish tracked during the summer, 36 fish were known to expire, 4 fish were never located and 5 fish were assumed to be alive at the conclusion of the study (Table 2).

Survival of striped bass, with known fates, caught during the winter was good (92\%), but survival of striped bass caught during the summer was poor (12\%). It appears that tube residence time during the winter does not effect survival. However, during the summer none of the fish held in tubes for more than 2 hours survived.

Dr. Joe Tomasso at Clemson University is currently analyzing blood samples to determine if striped bass recovered from capture after being held in tubes. The results of the blood work will be available next year.

Table 1. Striped bass collected with angling gear from Lake Murray, South Carolina, during winter and summer 2003, and used for the blood component of the evaluation of live-release tubes. Depth indicates the depth of the fish at capture ("Free" indicates angling depth was not controlled). Time in represents the time the fish was placed in a tube and time out represents the release time. Residence time is the amount of time, in hours, a fish spent in the tube. Fish with no residence time were not placed in tubes before having blood drawn.

Table 2. Striped bass collected with angling gear from Lake Murray, South Carolina, during winter and summer 2003, and fitted with transmitters. Depth indicates the depth of the fish at capture ("Free" indicates angling depth was not controlled). Residence time is the amount of time, in hours, a fish spent in the tube. Fish with no residence time were not placed in tubes. "Locs" is the number of times a fish was located and "MDA" is the minimum days alive. Fate codes are: $\mathrm{A}=$ assume fish was alive at end of study, $\mathrm{U}=$ unknown, and $\mathrm{D}=$ fish died during the study.

## Recommendations

Continue study as planned. The fieldwork for this project has been completed. We are awaiting the blood analysis so a completion report can be drafted. Preliminary analysis indicates that the evaluated tubes may offer tournament anglers the opportunity to conduct catch and release tournaments during the cooler months, but not the warmer months. Additional work on tube design and survival during the spring and fall transitional periods is needed.
